RESEARCH IN PROGRESS

Information concentration, correlation neglect and financial markets Job market paper

Abstract: As the informational landscape grows increasingly intricate, forming accurate beliefs becomes progressively challenging, a concern exacerbated by the recent rise in retail investors' activity. One dimension of technologically driven informational complexity is the rapid and sizeable replication of information across online outlets, which may result in misinterpreting repeated information as new. To address this question, I propose an asset pricing model with agents categorized into belief groups that receive a private signal containing group-level noise. Agents neglect the correlation between the signals they receive and those of their peers, which results in an overreaction to new information that positively affects price informativeness, reducing return volatility. Consistent with existing empirical evidence, this model predicts higher trading and negative subsequent returns. Information concentration is linked to the severity of the bias, which is highest under concentrated yet non-unique information and lowest when the information HHI approaches zero.

A model with financial advice and heterogeneously sophisticated agents
